¹Laboratorio de Ictiología, Departamento de Ciencias Marinas, Universidad Nacional de Mar del Plata, Funes 3350, Mar del Plata, B7602AYL, Argentina, ²Comisión de Investigaciones Científicas del Gobierno de la Provincia de Buenos Aires (CIC), Calle 526 e/10 y 11, La Plata, B1906APN, Argentina, ³Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Avenida Rivadavia 1917, Ciudad Autónoma de Buenos Aires, C1033AAJ, Argentina, ⁴Centro de Investigaciones Ecológicas Subtropicales (CIES) and Centro de Investigaciones del Bosque Atlántico (CeIBA), Casilla de Correo 9, Puerto Iguazú, N3370AVQ, Misiones, Argentina

The feeding habits of the Rio skate, Rioraja agassizi, from off Uruguay and north Argentina were evaluated using a multiple-hypothesis modelling approach. Relationships between number of preys and sex, maturity stage, body size, season and region were assessed by building generalized linear models. Rioraja agassizi fed mainly upon crustaceans (shrimps, crabs and amphipods) and teleosts, but also upon isopods, cumaceans, lancelets and polychaetes. Ontogenetic diet shifts were found: small R. agassizi consumed amphipods, cumaceans and isopods and large individuals on shrimps, crabs and teleosts. The consumption of crustaceans (amphipods, shrimps, crabs, isopods and cumaceans) was higher in the northern (34°–38°S) than in the southern area (38°–41°S). Rioraja agassizi consumed more teleosts in the cold season and preyed more on lancelets in the warm season. Prey size increased with increasing body size of R. agassizi, but large individuals also consumed small prey. Ontogenetic shifts may be related to body size rather than other life-history traits. Rioraja agassizi adapts its feeding habits in response to regional and seasonal changes.

Keywords: skates, feeding ecology, diet shifts, south-west Atlantic

Submitted 22 February 2010; accepted 2 August 2010; first published online 18 October 2010

INTRODUCTION

The Rio skate, *Rioraja agassizi* (Müller & Henle, 1841), is a common endemic skate from coastal waters distributed along the south-west Atlantic coast from Cabo Frio (20°S, Brazil) to Península Valdés (42°S, Argentina) (Menni & Stehmann, 2000). Taxonomy, distribution and some aspects of the reproductive biology of *R. agassizi* have been well studied off north Argentina and Uruguay (Colonello *et al.*, 2007; Estalles *et al.*, 2008). *Rioraja agassizi* is one of the most important skates caught as by-catch in the bottom trawling fishery that operates in this region (Massa *et al.*, 2004; Tamini *et al.*, 2006). The abundance of *R. agassizi* likely declined significantly and this species is categorized as vulnerable by the International Union for the Conservation of Nature (IUCN) (Kyne *et al.*, 2007).

The feeding habits of *R. agassizi* have been studied on the continental shelf off Ubatuba, Brazil, indicating that the species fed upon a wide variety of preys, mostly crustaceans (e.g. shrimps, crabs and amphipods), fish and polychaetes (Soares *et al.*, 1999; Muto *et al.*, 2001). Muto *et al.* (2001) also found ontogenetic shifts and variation among seasons in the diet composition of *R. agassizi*. In Argentinean and Uruguayan waters, a previous study on the diet composition

of *R. agassizi* showed that it preys mainly on crustaceans, followed by polychaetes and teleosts (Loez & Schang, 1982), but this study had a low sample size and samples obtained from a restricted area.

The aims of this study are to provide a quantitative analysis of the diet composition of *R. agassizi*, to assess the effects of sex, maturity stage, body size, season and region on the diet and also to evaluate predator–prey size relationships. Knowledge on diet composition and trophic relationships are essential for the implementation of ecosystem-level models (Braccini, 2008).

MATERIALS AND METHODS

Study area and sampling

The study area, between 34° and 41°S, consists of two coastal systems: (1) a stratified coastal zone (north of 37°S) influenced by the discharge of the Río de la Plata River; and (2) a homogeneous coastal zone (south of 37°S), that comprises an estuarine system, called El Rincón, characterized by the discharge of the Negro and Colorado Rivers and discharges of high-salinity waters of the San Matías Gulf (Guerrero & Piola, 1997; Lucas *et al.*, 2005).

Skates were collected from scientific trawl surveys (N = 252) conducted by the Instituto Nacional de Investigación y Desarrollo Pesquero (INIDEP, Argentina), and from

commercial landings ($N = 374$) (Figure 1). Research cruises were conducted in December (2005), February (2006) and June (2006). Commercial catches by the coastal fleet of Mar del Plata harbour were sampled during 2006 (September, October and November) and 2007 (April, May, July, August, October, November and December). For each individual captured, total length (TL, mm), sex and maturity stage were recorded. Maturity stage (juvenile or adult) was determined according to the degree of calcification of the claspers and the development of testes and reproductive ducts in males, and to the presence of eggs and observation of the uteri, oviducal glands and ovarian follicles in females (Stehmann, 2002; Colonello *et al.*, 2007). This species reaches maturity at between 495–577 mm and 420–520 mm of TL for females and males, respectively (Colonello *et al.*, 2007; Estalles *et al.*, 2008). The stomachs were excised and frozen at -20°C for subsequent analyses in the laboratory.

Diet composition and data analysis

Stomach contents were sorted and identified to the lowest possible taxon using published catalogues. Preys were counted and their wet weights recorded (± 0.01 g). When possible, TL of teleosts, carapace width (CW) of brachyuran crabs and cephalothorax length (CL) of shrimps were measured.

To evaluate the importance of each prey and allow for comparisons with other studies we calculated the following indices: percentage by number (%N), percentage by mass (%M), percentage frequency of occurrence (%FO) and index

of relative importance (IRI) (Pinkas *et al.*, 1971). IRI was expressed in percentage (%IRI; Cortés, 1997).

Sample size by sex, maturity stage, season and region was plotted against the mean cumulative Shannon–Wiener diversity index, randomized 100 times (Magurran, 2004), to determine whether a sufficient number of skates was sampled. Sample size was considered sufficient to describe diet and to conduct statistical analyses if the cumulative Shannon–Wiener diversity index reached an asymptote.

For the statistical analyses, preys were grouped into eight zoological categories: shrimps, brachyuran crabs, amphipods, isopods, cumaceans, lancelets, polychaetes and teleosts. These categories included prey with %FO ≥ 4 . We evaluated if the consumption of the prey categories varied with sex, maturity stage, body size (TL), season (warm = October–March; cold = April–September) and region (north = 34° – 38°S ; south = 38° – 41°S) using a multiple-hypothesis modelling approach (Anderson *et al.*, 2000; Franklin *et al.*, 2001; Johnson & Omland, 2004).

For each prey category, we built generalized linear models (GLM; Venables & Ripley, 2002) where the response variable was the number of prey consumed and the independent variables were sex, maturity stage, TL, season and region (Lucifora *et al.*, 2009a). Models with combinations between sex + season, sex + region, maturity stage + season, maturity + region, TL + season, TL + region and season + region as independent variables, were also fitted. We also fitted a model without any of the independent variables (i.e. null model) to test the hypothesis that none of the variables tested had an effect on the consumption of a prey category

Fig. 1. Map of study area showing positions of trawl stations (black circles) and cells of the fishing grid (black rectangles) where individuals of *Rioraja agassizi* were collected off Uruguay and north Argentina. The 50 m and 200 m isobaths are shown as solid and dashed lines, respectively. The rectangle in the inset shows the location of the study area in South America.

(Lucifora *et al.*, 2009b). Models have a negative binomial error distribution because there were too many zeros and the variance was often much greater than the mean, and a log link (Crawley, 2005). For each competing model, we calculated the Akaike information criterion (AIC) and the model with the lowest AIC was selected as the best model (Crawley, 2005). To obtain the likelihood of each competing model, Akaike's weight (w) was calculated (Franklin *et al.*, 2001; Johnson & Omland, 2004). If w did not provide strong support for any competing model, we computed model averaging (Johnson & Omland, 2004).

Predator-prey size relationships

Relationships between predator length and prey size were assessed using TL of skates and TL of teleost fish, CW of brachyuran crabs and CL of shrimps. We fitted regressions on the

5, 50 and 95% quantiles, in order to test an increase in minimum, medium and maximum prey size with increasing TL of skates, respectively (Scharf *et al.*, 1998).

RESULTS

Of the 626 skates sampled, 465 (74.28%) had food in their stomachs. Of the skates with food remains, 265 were females (246–710 mm TL) and 200 were males (240–616 mm TL). Overall, 4680 preys with a total weight of 2644.7 g were found in the stomachs. The cumulative curves of diversity reached an asymptote for all groups, indicating that sample sizes were sufficient (Figure 2).

The diet of *R. agassizi* was composed of 61 prey species: 25 decapods, 14 teleosts, five isopods, four molluscs, three amphipods, three cumaceans, three polychaetes, one chondrichthyan,

one misidacean, one lancelet and one sponge. *Rioraja agassizi* fed mainly on crustaceans (decapods, amphipods and cumaceans) and teleosts (Table 1). The most important prey by number was amphipods. The second major prey in terms of number was shrimps of the species *Artemesia longinaris*. The third major prey in number was cumaceans of the family Bodotriidae. Teleosts were the most important prey in terms of weight, with *Raneya brasiliensis* being the principal prey species. *Artemesia longinaris* was the second prey species by weight. In terms of percentage frequency of occurrence, shrimps were the most important prey, followed by teleosts and amphipods. Lancelets and polychaetes were also important preys by frequency of occurrence. Chondrichthyans, misidaceans, isopods and molluscs were less important components of the diet.

Relationships between number of prey consumed with maturity stage, TL, season and region were found (Table 2). The consumption of all prey categories was independent of sex. The consumption of shrimps, brachyuran crabs and teleosts increased with increasing TL of *R. agassizi* (Figures 3 & 4). On the contrary, the consumption of amphipods decreased with increasing TL of *R. agassizi* (Figure 3). Juveniles preyed on isopods and cumaceans more heavily than adults (Figure 5). Crustaceans (i.e. shrimps, brachyuran crabs, amphipods, isopods and cumaceans) were more consumed in the northern region than in the southern region (Figures 3 & 5). The number of teleosts consumed was higher in the cold season than in the warm season (Figure 4). On the other hand, the consumption of lancelets was higher in the warm season than in the cold season: lancelets were also

consumed more often in the south than in the north (Figure 6). Polychaetes had no significant relationship with any of the independent variables evaluated. The hypothesis of consumption of both isopods and cumaceans has a low *w*, so we computed model averaging for these models. The averaged coefficients of isopods were 1.030 (standard error = 0.577) for juveniles and -0.740 (standard error = 0.662) for the south region, with a combined *w* of 0.75. For cumaceans, the averaged coefficients were 2.771 (standard error = 6.832) for juveniles and -3.621 (standard error = 6.887) with a combined *w* of 0.71.

Minimum and median CL of shrimps increased significantly with the TL of skates (5% quantile regression slope = 0.017, $t = 2.238$, $P = 0.027$; 50% quantile regression slope = 0.021, $t = 2.398$, $P = 0.018$) (Figure 7). The maximum CW of brachyuran crabs consumed increased significantly with the TL of skates (95% quantile regression slope = 0.158, $t = 0.061$, $P = 0.013$) (Figure 7). As TL of skates increased, both median and maximum TL of teleosts increased significantly (50% quantile regression slope = 0.674, $t = 5.251$, $P = <0.01$; 95% quantile regression slope = 0.805, $t = 5.134$, $P = <0.01$) (Figure 7).

DISCUSSION

The feeding habits of *R. agassizi* are demersal–benthic: it feeds mainly on amphipods, decapods (shrimps and brachyuran crabs) and teleosts, followed by isopods, cumaceans, lancelets and polychaetes. *Rioraja agassizi* showed changes in the diet

Table 2. Best models explaining the consumption of prey category in number of *Rioraja agassizi*. The intercept and coefficient for the variables are given. TL, total length (mm); AIC, Akaike information criterion; *w*, Akaike's weights; standard errors in parentheses.

Prey categories	Intercept	Coefficients	AIC	<i>w</i>

important prey were crustaceans, like shrimps, amphipods and brachyuran crabs, whereas polychaetes and teleosts were less important. It contrasts with our results, where amphipods, decapods and teleosts are equally important. The most important prey species by Loez & Schang (1982) was the shrimp *Pleoticus muelleri*, whereas it was the shrimp *Artemesia longinaris* in the present study. This difference in the most important prey species may be due to differences in sampling areas: Loez & Schang (1982) reflected the diet of the more localized subpopulation of skates, since they took their samples in a very restricted area and the samples of this study covered a much larger area.

In coastal Brazilian waters some studies were conducted on the diet composition of *R. agassizi* (Soares *et al.*, 1992, 1999; Muto *et al.*, 2001). In Ubatuba Bay (24°S), shrimps were the main prey, followed by teleosts and polychaetes, while amphipods were less important (Soares *et al.*, 1992; Muto *et al.*, 2001). Soares *et al.* (1999) found that the diet of *R. agassizi* in Ubatuba Bay consisted of shrimps and brachyuran crabs, while polychaetes and teleosts were less important. These patterns found in Brazilian waters contrast in part with our results because the main preys in the overall diet off Uruguay and north Argentina are amphipods and teleosts.

An important pattern to note is the consumption of lancelets by *R. agassizi* because there are no records of the consumption of lancelets by other skate species. Lancelets are consumed off Uruguay and northern Argentina by other chondrichthyan species, like the shortnose guitarfish, *Zapteryx brevirostris* (Barbini, 2006) and the apron ray, *Discopyge tschudii* (García, 1984). Lancelets live buried or semi-buried in the substratum (Lambert, 2005), like polychaetes (Rouse & Pleijel, 2001). The consumption of these preys suggests that *R. agassizi* digs into the bottom in search of preys.

Individuals of small body size and juveniles of *R. agassizi* feed on small crustaceans, like amphipods, isopods and cumaceans. As body size increases *R. agassizi* consumes larger and faster preys, such as shrimps, brachyuran crabs and teleosts. A similar pattern was found for *R. agassizi* from off Mar del Plata, Argentina (Loez & Schang, 1982) and from Ubatuba Bay, Brazil (Muto *et al.*, 2001). Ontogenetic shifts are a

Fig. 7. Quantile regressions of cephalothorax length (CL) of shrimps, carapace width (CW) of brachyuran crabs, total length (TL) of teleost fish and total length of *Rioraja agassizi*. The dotted, dashed and solid lines are 5%, 50% and 95% quantile regressions, respectively.

pattern widely observed in skates (Lucifora *et al.*, 2000; Morato *et al.*, 2003; Orlov, 2003; Robinson *et al.*, 2007; Belleggia *et al.*, 2008; Ruocco *et al.*, 2009) and these results are more a function of body size (e.g. mouth size and swimming speed) rather than of other life-history traits (Farias *et al.*, 2006; Treloar *et al.*, 2007).

The diet composition of *R. agassizi* showed regional and seasonal variation. The regional pattern is characterized by a higher consumption of crustaceans (i.e. shrimps, crabs, amphipods, isopods and cumaceans) in the northern region than in the southern region. This regional difference may be explained by environmental differences between regions. The structure, dynamic, richness and abundance of the benthic community of the northern region may be different than that of the southern region, possibly caused by distinct physical variables (D. Giberto, personal communication). In the north area, the Río de la Plata estuary, bottom type, salinity and the presence of a turbidity front are considered the main variables structuring the benthic communities of this area (Giberto *et al.*, 2004). On the other hand, the south area is characterized by vertical homogeneity due to tidal forcing and a salinity coastal front that is maintained by the bathymetry and the mean shelf circulation (Acha *et al.*, 2004).

Species composition of benthic and demersal coastal communities is variable, since the distribution and abundance of many species of the marine fauna changes seasonally (Jaureguizar *et al.*, 2006). Seasonal changes in the diet of *R. agassizi* are due to a higher consumption of teleosts in the cold season and an increase in the consumption of lancelets in the warm season. The seasonal variability of the abundance of teleosts (i.e. *Raneya brasiliensis*, *Dules auriga* and *Etropus longimanus*) and lancelets consumed by *R. agassizi* in the area is unknown and needs further studies. However, this pattern may be probably attributed to fluctuations in the abundance and distribution of the preys (Muto *et al.*, 2001; Rinewalt *et al.*, 2007). Seasonal variations in diet have been reported for other skates in the region (e.g. *Psammobatis extenta*, Braccini & Perez, 2005; *P. bergi*, San Martín *et al.*, 2007). In Ubatuba Bay, *R. agassizi* also exhibits seasonal variations in the diet composition associated to a peak in the abundance of its main prey (Muto *et al.*, 2001). These patterns indicate that *R. agassizi* is a plastic and versatile predator, adapting its feeding habits in response to regional and seasonal changes.

The size of the consumed prey increases with the size of *R. agassizi*. As *R. agassizi* increases its body size, the size of the shrimps, brachyuran crabs and teleosts increases too, but the skate do not abandon the consumption of small brachyuran crabs and teleosts. Differences in prey availability may explain the different patterns found in these preys. The shrimps *A. longinaris* and *P. muelleri* are abundant preys in this region (Giberto *et al.*, 2004), then large *R. agassizi* may be more selective, consuming only larger shrimps. On the other hand, the lower availability of crabs and teleosts together with a higher vulnerability of these small preys (i.e. higher probability of capture; Scharf *et al.*, 2000; Lucifora *et al.*, 2006), may explain the continuous inclusion of small crabs and teleosts in stomach contents of large *R. agassizi*. A similar pattern was present in other elasmobranchs, mainly piscivorous sharks (Scharf *et al.*, 2000; Lucifora *et al.*, 2006, 2009a; Baremore *et al.*, 2010) and not in another skate, *Zearaja chilensis*. The size of preys consumed by the latter species increased with increasing predator size and small preys are not consumed by large skates (Lucifora *et al.*, 2000; Koen Alonso *et al.*, 2001).

The diet of *R. agassizi* was composed mainly of prey with benthic affinities, such as teleosts (e.g. *Etropus longimanus*), brachyuran crabs (e.g. *Ovalipes trimaculatus*, *Leurocyclus tuberculatus* and *Libinia spinosa*) and small invertebrates

(e.g. amphipods, cumaceans, isopods and polychaetes) and also demersal-benthic prey, including shrimps (e.g. *Artemesia longinaris* and *Pleoticus muelleri*) and teleosts (e.g. *Raneya brasiliensis* and *Dules auriga*). Thereby, *R. agassizi* have a strong predatory interaction with the benthic community. Coastal areas from Uruguay and north Argentina are exposed to a high intensity of bottom trawling (Cousseau & Perrotta, 2000; Brazeiro *et al.*, 2003). This fishing gear alters the physical structure of the habitat, affecting the benthic ecology of the bottom (Kaiser, 1998; Watling & Norse, 1998), generating potential indirect effects on the fish community (Brazeiro *et al.*, 2003), and altering the abundance and availability of preys for *R. agassizi*.

ACKNOWLEDGEMENTS

We are grateful to the Instituto Nacional de Investigación y Desarrollo Pesquero (INIDEP) for specimens collected during various research cruises. We also thank M. Scelzo and R. Elías (Universidad Nacional de Mar del Plata) for their help in identifying crabs and polychaetes, respectively, and 2 anonymous referees for helpful comments that greatly improved the paper. S.A. Barbini was supported by a scholarship from CIC.
